Hand Surgery for Contractures

Restoring Function
When Your Problem Gets Out of Hand

Your hands play a vital role in nearly everything you do. So when something goes wrong with your hands, it can disrupt your daily routine. Hand problems can cause pain or impair function, making it hard for you to carry on your normal activities.

**Contractures**

One common hand problem is called **contractures**. This is loss of some motion in a finger or thumb. If this problem interferes with your daily life, it may be time to consider surgery.

Your surgeon will help you decide if surgery is your best treatment option. Your doctor may have tried other treatments such as a splint or cortisone injections. But when that didn’t completely solve your problem, your doctor suggested surgery. This may be the best option to relieve your pain and restore movement and function in your hand. Your surgeon has the special skills necessary to successfully treat your problem.

**Learning More**
Your hand is made up of many parts. Read on to learn more about how your hand works, what is causing your problem, and the tests you might have. You’ll also learn what to expect before, during, and after surgery. This can help you make decisions about your treatment.
An Inside Look at Your Hands

Your hands are made up of more bones and moving parts than most other areas of your body. When they’re healthy, all of these parts work together to perform many kinds of tasks—from delicate movements to acts of strength. By learning how the parts of a healthy hand work together, you’ll better understand what’s causing your problem.

Back view of your left hand
Place your left hand next to the drawing below, and picture the parts just below the surface of your skin. Slowly bend a finger. It’s your joints and muscles that allow you to do that.

- **Bones** are hard tissues that give your hand shape and stability.
- **Phalanges** (finger bones)
- **Metacarpals** (hand bones)
- **Carpals** (wrist bones)
- **Joints** are places where bones fit together, allowing movement.
- **Ligaments** are soft tissues that connect bone to bone and stabilize your joints.
- **Muscles** are soft tissues that **contract** (tighten) and relax to move your hand.
- **The synovial lining** produces the fluid inside your joints that makes movement smooth.
Palm view of your right hand
Place your right hand next to the drawing below and gently try to bend a finger backward. You can’t bend it far because the volar (palmar) plate keeps it from moving in that direction.

- **Volar plates** are hard tissues that stabilize the joints, keeping fingers from bending backward.
- **Tendon sheaths** are fluid-filled tubes that surround, protect, and guide the tendons.
- **Tendons** are cordlike soft tissues that connect muscle to bone.
- **Blood vessels** carry blood to and from your hand.
- **Nerves** send and receive messages that allow you to feel and help coordinate movement.

**The palmar fascia** is a firm layer of soft tissue that stabilizes the palm of your hand.

**Your Hands at Work**

**Moving**
Muscles, tendons, nerves, and bones all work together to control delicate hand movements, like those you use to play the piano or type.

**Gripping**
Muscles and bones work with the palmar fascia to give you the strength to grip and lift heavy objects.

**Touching**
Nerves in your hands are so sensitive that they can help you tell the difference between a nickel and a quarter, even when you’re not looking at them.
Your Medical Evaluation

To make a diagnosis, your surgeon does an evaluation. This may include your medical history, a hand exam, and tests such as x-rays or nerve tests.

Medical History
Your surgeon may ask about your general health, and for details about any recent hand injuries. He or she may also want to know the kinds of tasks you perform on the job, since many hand injuries are work-related.

The Hand Exam
Your surgeon will closely examine your hand. He or she will look for signs of infection, sensitive areas, and places where function and movement are impaired. Your hand’s range of motion (how much the fingers and hand can bend and straighten) will also be tested.

X-rays
To confirm a diagnosis, your surgeon may order x-rays, nerve tests, or other imaging tests to see what’s happening inside your hand.

Choosing Surgery
Together, you and your surgeon will decide whether your hand problem can best be treated with surgery. Most hand problems are not emergencies, so you can usually schedule surgery when it’s convenient.
Your Surgical Experience

The surgery to treat the contractures may be done in your surgeon’s office, a hospital, or an outpatient surgical center. The type of surgery will determine whether you can go home the same day, or need to stay overnight in the hospital.

Planning Ahead
To make recovery easier:

- Shop ahead for disposable plates and foods such as frozen dinners.
- Sign some checks ahead of time if the surgery will be on the hand you write with.
- Arrange for someone to drive you home after surgery.
- Ask your surgeon how long you will need to be away from work.

Before Surgery
To reduce the risk of complications:

- Stop smoking and don’t take any aspirin for at least 1 week before surgery.
- Don’t eat or drink anything (even water) for 8 hours before surgery.

During Surgery
Your surgeon will talk with you about the type of anesthesia you will receive during surgery. A **general anesthetic** lets you sleep. A **regional anesthetic** numbs your hand and arm. A **local anesthetic** numbs just the area of surgery. With local anesthesia, you may feel some discomfort from the **tourniquet** (cuff) on your arm, which is needed to prevent blood flow to your hand during surgery.

Risks and Complications
Your surgeon will discuss the risks of surgery with you, including:

- Excessive bleeding
- Severe swelling
- Unrelieved pain
- Impaired circulation
- Tingling or numbness
- Impaired movement
- Infection
Surgery for Contractures

A contracture of the hand, finger, or thumb is a condition that leads to decreased range of motion. It can be inherited or the result of an injury. If a finger won’t straighten properly, it can be difficult to use the hand. Your surgeon can help relieve pain and restore motion by removing, repairing, or replacing the tissue that’s causing the contracture. The size and location of the scar will vary, depending on the type of procedure you have. After surgery, your surgeon may prescribe hand exercises or therapy to do under the guidance of a hand therapist. This can help you regain normal movement and function in your hand.

**Condition**

**Dupuytren’s Contracture**

Dupuytren’s contracture is an abnormal thickening of the palmar fascia near the ring and little fingers. It can be an inherited disease, and is most often found in middle-aged people of northern European ancestry. The condition is painless, but it often restricts movement so much that the fingers can’t straighten.

**Condition**

**Flexor and Extensor Tendon Injuries**

Tendons of the fingers and hand can be injured by cuts. They can also be torn or snapped when a finger is yanked or jerked. During the surgery, your surgeon will rejoin the two ends of the tendon and repair any other damaged tissue. In some cases, new tendon will be grafted to replace the old one.

**Problem**

A cut tendon causes the finger to lose its function.

**Procedure**

The ends of the tendon are reattached.

**Result**

Hand therapy after surgery helps the finger heal and function better.

---

**Condition**

**Basal Joint Arthritis**

The basal joint, in the lower part of the thumb, is commonly affected by arthritis. The joint becomes inflamed and slowly wears out. Pinching and grasping become very painful, sometimes impossible. Common surgeries for this condition include excisional arthroplasty (pictured on the right) and artificial joint replacement.

**Problem**

The joint is so irritated and swollen that pinching and grasping are difficult and painful.

**Procedure**

The diseased joint is removed. It is replaced with a tendon graft (a piece of tendon from your arm or wrist).

**Result**

With the tendon graft in place, you’ll have less pain and be able to use your thumb again.
After surgery, the better you take care of yourself—especially your hand—the sooner it will heal. Follow your surgeon’s instructions. Try not to bump your hand, and don’t move or lift anything while you’re still wearing bandages, a splint, or a cast.

Keep It Up
Keep your hand elevated above heart level for the first several days after surgery. This helps reduce swelling and pain.

Keep It Dry
To help prevent infection and speed healing, take care not to get your cast or bandages wet.

Keep your hand elevated to reduce swelling and help your hand heal.

Keep your hand dry while bathing by wrapping your hand in plastic and securing it with tape.

Relieve the Pain
Your surgeon may prescribe pain medication or suggest you take an anti-inflammatory medication. You might also be instructed to apply ice (or another cold source) to your hand. If you use ice cubes, put them in a plastic bag and rest it on top of your bandages. Leave the cold source on your hand for as long as it’s comfortable. Do this several times a day for the first few days after surgery. It may take several minutes before you can feel the cold through the cast or bandages.
Follow Up with Your Surgeon

During a follow-up visit after surgery, your surgeon will check your progress. The stitches, bandages, splint, or cast may be removed. Or a new cast or splint may be placed. If your hand has healed enough, your surgeon may prescribe exercises.

Hand Exercises

Your surgeon may recommend that you do exercises. These may be done under the guidance of a physical therapist. The exercises strengthen your hand, help you regain flexibility, and restore proper function. Do the exercises as advised.

Squeezing a sponge helps restore your hand’s flexibility.

A splint helps you regain finger joint extension (the straightening motion).

Your surgeon will usually remove your bandages within 2 weeks after surgery.

Call your surgeon if you have...

- A fever higher than 100°F (37.7°C).
- Side effects from your medication, such as prolonged nausea.
- A wet or loose dressing, or a dressing that is too tight.
- Excessive bleeding.
- Increased, ongoing pain or numbness.
- Signs of infection (such as warmth or redness) at the incision site.
Give Yourself a Hand

You can play an active role in your recovery and help ensure your return to everyday activities—both at home and at work. Taking good care of your hands will help them work (and play) for you for a lifetime.
